PHYS 610: Electricity & Magnetism I Due date: Thursday, April 13, 2017

### Problem set #9

### 1. Free space Green's functions by eigenfunction expansion

Find the free-space Green's function by eigenfunction expansion for the following 3 situations:

a) dimension=3.

b) dimension=2.

Note: you will need (i) an integral representations of  $J_0(x)$  and  $K_0(x)$  and (ii) the regularization  $1/k = \lim_{\delta \to 0} k/(k^2 + \delta^2)$ .

c) dimension=1.

Note: you will need  $sgn(x) = -1 + 2 \int_{-\infty}^{x} \delta(y) dy$ .

# 2. Potential on a sphere

The potential on the surface of a sphere of radius R is given in spherical coordinates by

$$V(r = R, \theta, \phi) = V_0 \cos(3\theta)$$

a) Find the potential inside and outside the sphere (note:  $V_0$  is a constant).

b) Find the surface charge density on the sphere (assume that all charge lies on the surface of the sphere).

#### 3. Electric field inside a sphere

Calculate the volume charge density  $\rho$  and surface charge density  $\sigma$  which must be placed in and on a sphere of radius R (no other charges are present) such that the electric field within the sphere is given by

$$\vec{E} = -2V_0 \frac{xy}{R^3} \hat{x} + \frac{V_0}{R^3} (y^2 - x^2) \hat{y} - \frac{V_0}{R} \hat{z}$$

Express your answer in terms of trigonometric functions of the  $\theta$  and  $\phi$  spherical coordinates.

#### 4. Planar boundary

Consider a conducting sheet in the x-y plane (i.e. z=0). The sheet is divided along the y-axis by a thin insulator, such that x < 0 and x > 0 portions of the sheet are at different potentials  $-V_0$  and  $V_0$ , respectively ( $V_0$  is a constant over each half sheet).

a) Use a spatial scaling argument to conclude that for z>0 the potential V(x, y, z) is independent of *r* and *y* (in cylindrical coordinates with a *y*-axis of symmetry).

b) Find the electrostatic potential  $V(\phi)$  in the z>0 region, and make a quantitatively accurate sketch of the electric field lines.

# 5. A little more Jackson
